NestUp

Find it. List it. Love it.

1. What is your system idea (in a nutshell)?

NestUp is aimed at small, independent real estate agencies running two to ten agents — the kind of office where nothing yet talks to anything else. Most agencies this size are still juggling a spreadsheet for listings, a paper diary for viewing bookings, a phone full of texts for offers, and a notebook for buyer preferences. Because none of these live in the same place, agents forget who has already seen a property, and vendors end up chasing the office for updates nobody can pull up on the spot.

NestUp pulls all of that into one relational database: every listing, every vendor and buyer, every viewing, and every offer. That means an agent can look up a property's or a client's entire history in seconds instead of digging through three different tools. What actually sets it apart from just using a spreadsheet is the buyer-matching feature: the moment a new property goes live, the system checks it against every buyer's saved criteria (budget, suburb, bedrooms, property type) and returns a list of who should get a call. Right now that cross-referencing eats up about twenty minutes of an agent's day; NestUp turns it into an instant list.

2. What information will the system offer the user?

Agents get a live view of everything on the agency's books: price, current status (listed, under offer, sold, withdrawn), how long it's been on the market, and the vendor's contact details. Every property also carries its full viewing history, so an agent can see exactly who came through and what they thought before making a follow-up call. The same goes for offers: every one ever made on a property is kept in order, so the negotiation trail survives even if the agent who took the first call is away.

Buyers who are registered get matched automatically. Agents can pull up a ranked shortlist of properties that fit a buyer's budget, suburb preference, and minimum bedrooms, and that list updates itself the moment a new listing appears or a price changes. Managers get a different view again: simple reports showing how many listings each agent has taken on, average days on market, and commission earned, so they can spot who might need support without having to ask around the office.

3. In order to achieve this, what data will be stored by the system?

An Agent record is name, phone number, email, and commission rate. Vendor records (the people selling a property) carry the same basics plus a link back to the property itself. Buyer records go further: name and contact details, sure, but also maximum budget, preferred suburbs, minimum bedrooms, and the type of property they're after (house, townhouse, apartment, or section).

Property records are the most detailed: street address, suburb, asking price, bedroom and bathroom count, land size, floor area, listing date, current status, a short description, and which vendor and agent are attached to it. Viewing records log the property, the buyer who attended, the agent who hosted, the date and time, and whatever feedback the agent notes down afterwards. Offer records hold the property, the buyer, the amount, the date, and a status (pending, accepted, declined, or countered), plus a link back to any offer it's countering, so the whole negotiation chain can be traced. Once an offer is accepted, a Sale record captures the final price, the settlement date, and the commission owed.

4. Where will you get this data?

Property details come from the listing agent, entered the moment a vendor signs on: address, price, and the rest go in the same way an agent would fill out a paper listing form today. Buyer and vendor contact information gets entered the first time someone reaches out to the agency, whether that's a phone call, a walk-in, or an enquiry through the agency's website.

Viewing feedback goes in straight after each open home or private viewing, while it's still fresh in the agent's mind. Offers get logged as soon as a buyer makes one, whether it came in by email, in person, or over the phone. None of this needs a live feed or an outside source. It's all information the agency is already gathering day to day; NestUp just gives it a single home instead of scattering it across a diary, a phone, and a spreadsheet.

5. List of Use Cases your system will implement

- Create, update, or take down a property listing.
- Filter current listings by suburb, price range, bedroom count, or status.
- Register a new buyer along with their budget and property preferences.
- Automatically check a new or updated listing against every registered buyer's saved criteria and generate a contact shortlist.
- Book a viewing for a property and log who's attending.
- Log a buyer's feedback after a viewing.
- Record a new offer on a property, or a counter-offer against one already on file.
- Change an offer's status (accepted, declined, or countered), and generate the linked Sale record once it's accepted.
- Work out the commission owed to the agent once a sale settles.
- Pull past sales by suburb and property type to build a comparable-sales list when pricing a new listing.
- Produce a monthly report per agent covering listings taken, viewings held, and sales completed.

6. Who are the target users/actors?

The people using NestUp day to day are the agents themselves, adding listings, booking viewings, and logging offers. Reception or admin staff usually take down a buyer's or vendor's details the moment someone calls or walks in, then pass them on to an agent. The branch manager barely touches data entry; they mostly live in the reporting side, checking how individual agents, and the agency overall, are tracking.

Buyers and vendors don't log into NestUp themselves in this version. They deal with it through the agent, by phone or in person. A future version could give them their own login to check live updates on a property or a shortlist, but that's left out for now to keep the first build realistic to actually deliver.

7. What comparable systems are currently available and how does your proposal differ from comparable systems?

New Zealand and Australia already have established real estate CRMs on the market: Rex, Vault CRM, Realbase, and AgentBox among them. They're built for the big end of the market: franchise networks like Ray White or Bayleys, with automated marketing campaigns, integration with realestate.co.nz and Trade Me listings, SMS marketing tools, and reporting that spans dozens of branches.

That scale is exactly the problem for a small independent agency: these platforms are priced per seat, take real time to set up, and most of what they offer never gets touched by an office running two to five agents who just want to track their own listings, buyers, and offers. NestUp goes the other way and stays small on purpose: no marketing automation, no portal integrations, no multi-branch reporting, because a small agency doesn't need any of it. The one feature it does lean into, automatic buyer-to-listing matching, is built for the actual daily problem these agencies have: working out which buyer on file to ring the second a new property lands.

8. Diagram: Problem Domain Sketch

The sketch below lays out the core entities in the NestUp problem domain and how they connect: an Agent manages a Property, a Vendor lists it, and Buyers get matched to it and view it. A Viewing can lead to an Offer, and once an Offer is accepted it becomes a Sale, which closes the Property off.
